I. SYNOPSIS

It is of interest to carry out a full calculation of the H_2^+ quantum mechanical energy as a function of the internuclear distance so that one understands that the 2-electron problem's difficulties are, at least partially, due to the electron-electron repulsion. We've done this already once with the ground state, but it seems worthwhile to look at π orbitals also, hence this reading.

II. INTRODUCTION

The p orbitals which combine to form π orbitals should be chosen from the set p_x and p_y , since the p_z orbitals are aligned along the z-axis, and therefore are cylindrically symmetric, and therefore combine to form σ orbitals, specifically p_σ and p_{σ^*} .

In our previous reading,
http://digitalcommons.uconn.edu/chem_educ/36, we've given the coördinate transformations so, here we write

$$\psi_{LCAO-MO} = p_x^A + p_x^B = xe^{-\alpha r_A} + xe^{-\alpha r_B}$$

in mixed notation (we put the protons arbitrarily at point A (0,0,R/2) and B (0,0,-R/2)).

$$r_A = \frac{R}{2}(\lambda + \mu)$$

and

$$r_B = \frac{R}{2}(\lambda - \mu)$$

while

$$x = \frac{R}{2} \cos \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)}$$

and

$$y = \frac{R}{2} \sin \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)}$$

so

$$\begin{aligned} \psi_{LCAO-MO} = & \frac{R}{2} \cos \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)} e^{-\alpha r_A} + \\ & \frac{R}{2} \cos \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)} e^{-\alpha r_B} \end{aligned} \quad (2.1)$$

which is, finally

$$\begin{aligned} \psi_{LCAO-MO} = & \frac{R}{2} \cos \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)} e^{-\alpha \frac{R}{2}(\lambda + \mu)} + \\ & \frac{R}{2} \cos \phi \sqrt{(\lambda^2 - 1)(1 - \mu^2)} e^{-\alpha \frac{R}{2}(\lambda - \mu)} \end{aligned}$$

From this definition (of the π , and with a minus sign, the π^*) we can continue, using essentially the same code as before.
