# Optimized Still Image Batch Processing of Special Collections Bound Monographs and Manuscripts Using DNG, JPEG 2000, and Embedded XMP Metadata

Michael J. Bennett; University of Connecticut Libraries; Storrs, CT/USA

## Abstract

Batch still image processing is examined in the context of operational bound monographs and manuscripts reformatting. The scaling of overall workflows through the flexible use of Lightroom, Photoshop, VueScan, and Jhove on parametrically-edited raw DNG and batch-rendered JPEG 2000 files is surveyed. Potential gains in processing efficiency, in comprehensive device data capture and preservation, in adaptable master image repurposing capabilities, and in the smoother growth of the required large-scale digital storage capacities that surround such operational conversions are considered.

## Introduction

Digital still image capture of archives and special collections' objects has often followed a traditional uncompressed TIFF archival copy > compressed JPEG access copy processing chain for many reformatting projects. Though this has operated well enough in most cases, newer image formats and metadata wrappers along with more powerful tools centered on such advances have allowed for novel image utilization and the re-evaluation of overall workflow efficiencies. In an ever expanding electronic environment, users are in search of richer digital content and have come to expect greater image quality for innovative manipulations and enhanced study. Within this ecosystem the obligations of content creators towards coherent production, storage, management, preservation, and more flexible and finely-tailored output of their own quickly growing digital archives and special collections have become magnified as a product of increasing overall scale. In turn, it naturally follows that novel value-added enhancements in workflow design, using the inherent capabilities of new still imaging formats, metadata specifications, and the latest developments in image editing software are engineered.

## DNG as RAW Safety Master File Format

When looking at raw image formats as the starting point of an overall digital imaging chain a number of scalable advantages over traditional TIFF-based archiving and raster processing become apparent. Though these are outlined in narrative depth elsewhere [1][2][3][4][5][6] a look at the current capture workflow of monographs and manuscripts employed at the University of Connecticut (UConn) Libraries may be pertinent.

## Bound Monograph Workflow: DNG from Camera Color Filter Array (CFA) [7][8] Sensor Data

In this example, page images of John Donne's 1611 *Conclave Ignati* are used. Proprietary Canon .CR2 camera raw files are first converted into a folder of DNG safety masters, segregated into left and right page Adobe Lightroom 3 Collections by either verso or recto page origin, and then losslessly rotated and cropped through synchronized Lightroom parametric [9] edits. Such DNG raw editing, particularly across large, homogeneous image groups, saves substantial processing time, overall CPU overhead, and required storage space against comparable raster image batch editing steps which, unless accomplished as unmerged layered TIFF or PSD files, are irreversible in final form. Raw DNGs can be losslessly compressed, can retain originally-captured sensor data even when parametrically edited, and in fact can quite easily be reversed back to their original latent, unedited state. In this manner, the format can adroitly serve as both a robust master and efficiently processed format.

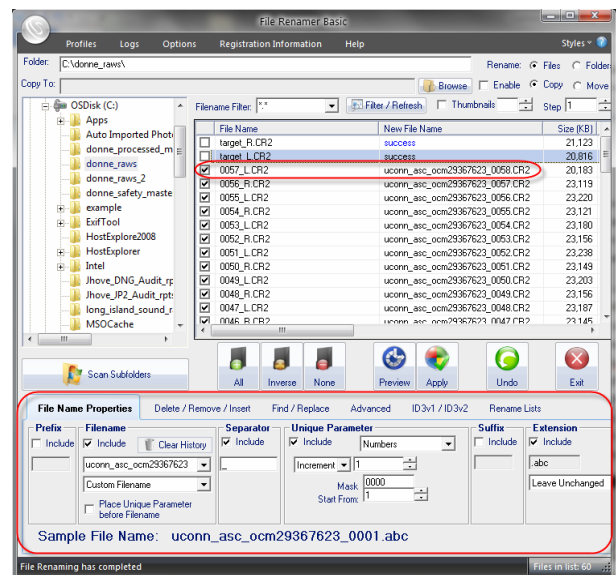

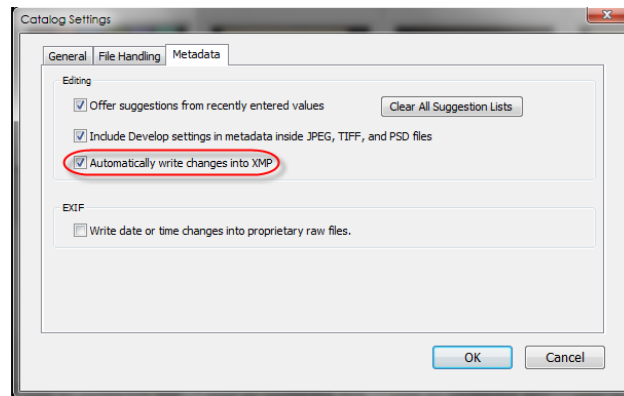

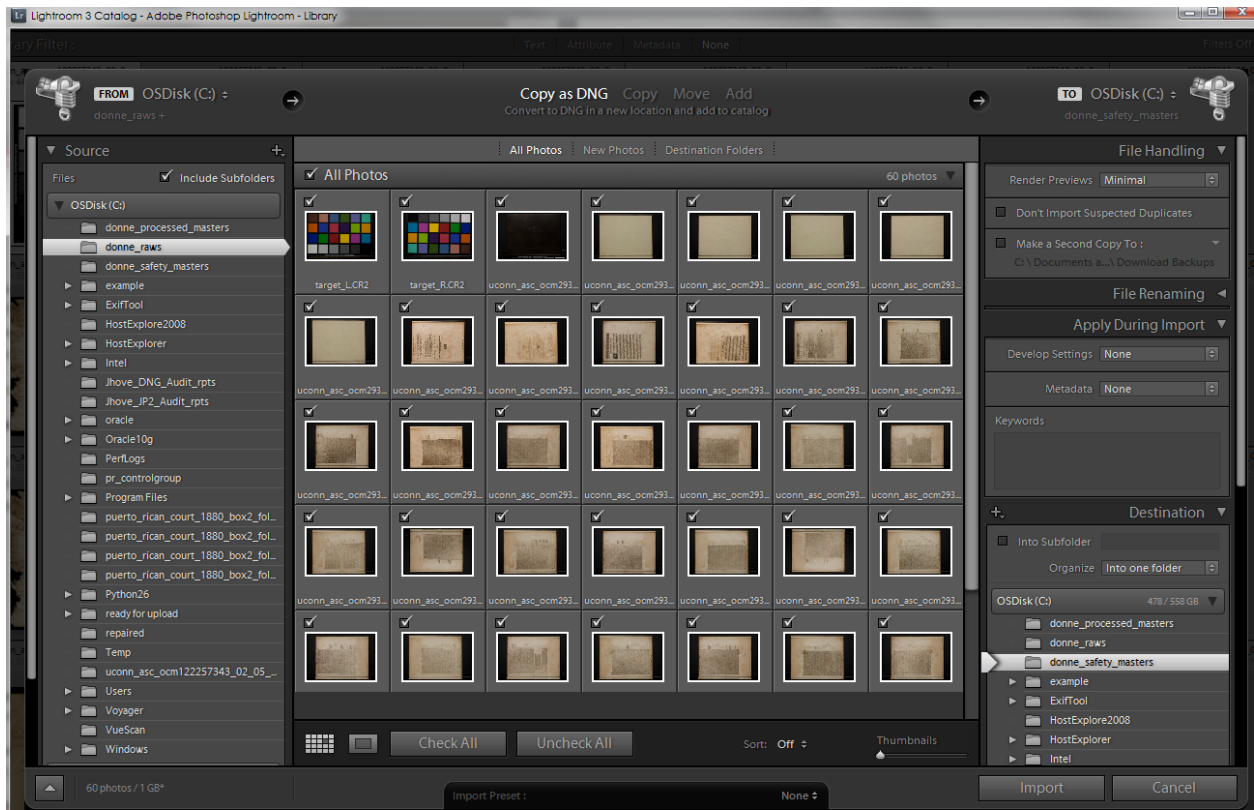

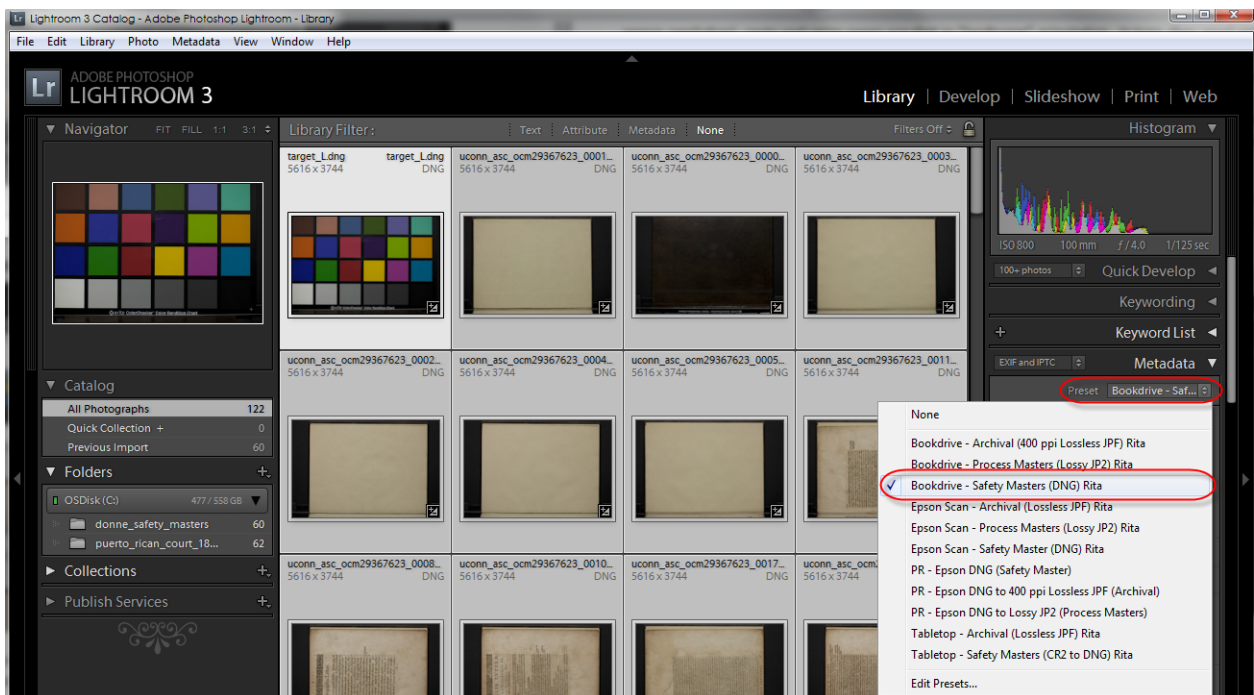

Figure 1. Camera raw files are renamed with local file naming convention [10]. This can be done in either Adobe Bridge, or in a dedicated renaming tool like FileRenamer.

**Figure 2.** Adobe Lightroom is opened and Catalog Preferences are set to “Automatically write changes into XMP.” This ensures that all subsequent parametric edits and added process metadata will be embedded in the newly-converted DNG files (see Figure 3) and not just stored in the Lightroom catalog database.

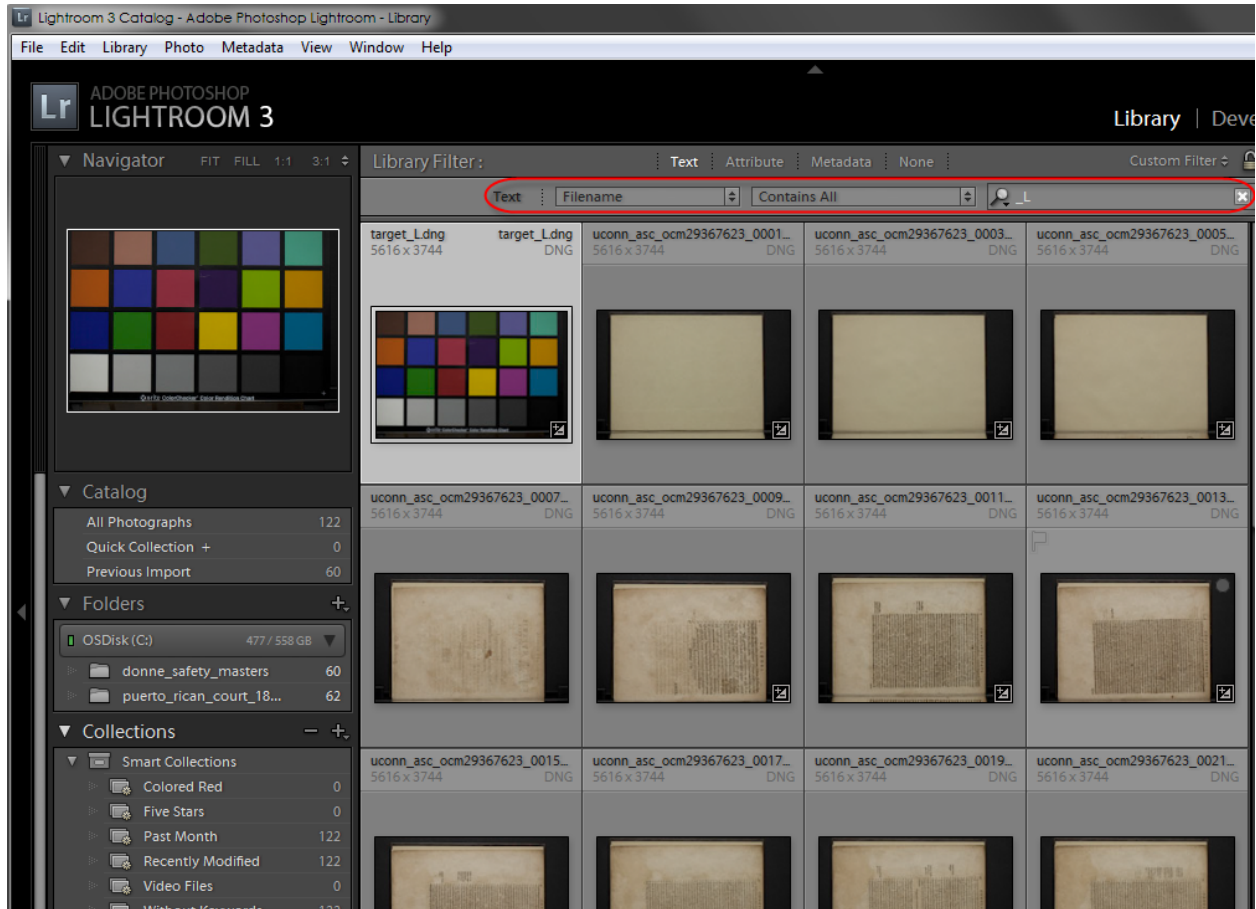

**Figure 3.** A new folder, c:\book\_title\_safety\_masters, is created. In Lightroom c:\book\_title\_raw (original camera raw images folder) is imported. During this process original camera raw files are batch converted to DNG and saved to a new destination folder, c:\book\_title\_safety\_masters. By default Lightroom accomplishes such DNG conversions (v1.3) with the lossless compression supported by the format.

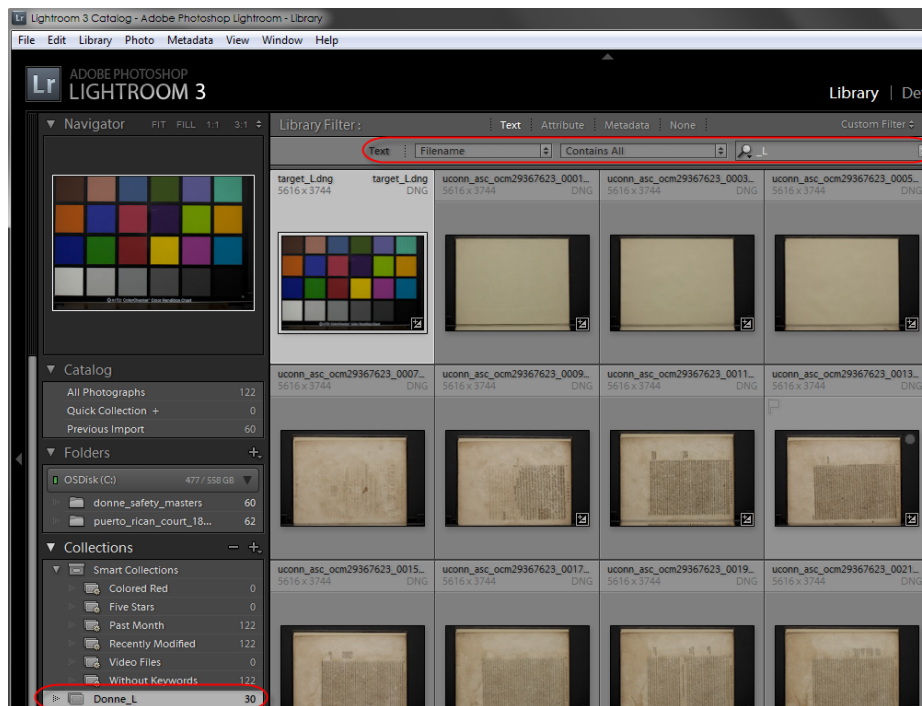

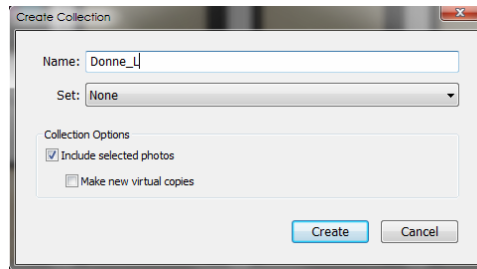

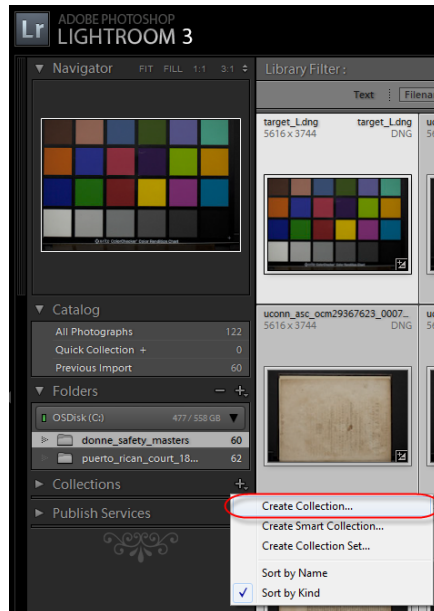

**Figure 4.** With all images selected, technical process metadata is added in a batch from a pre-made Lightroom metadata preset (see section V. for more details on the various process metadata templates used in the UConn Libraries lab).

At UConn, bound monographs are captured on Atiz BookDrive book cradles outfitted with dual Canon 5D II DSLR full-frame sensor cameras that shoot 3:2 aspect ratio images. As a result in order to minimize cropping (and the loss of maximum sensor sampling rate), recto and verso pages are shot in “landscape” orientation. In turn, they require either 90° clockwise or 90° counter-clockwise rotation to bring page text back into proper “portrait” reading alignment. To best facilitate

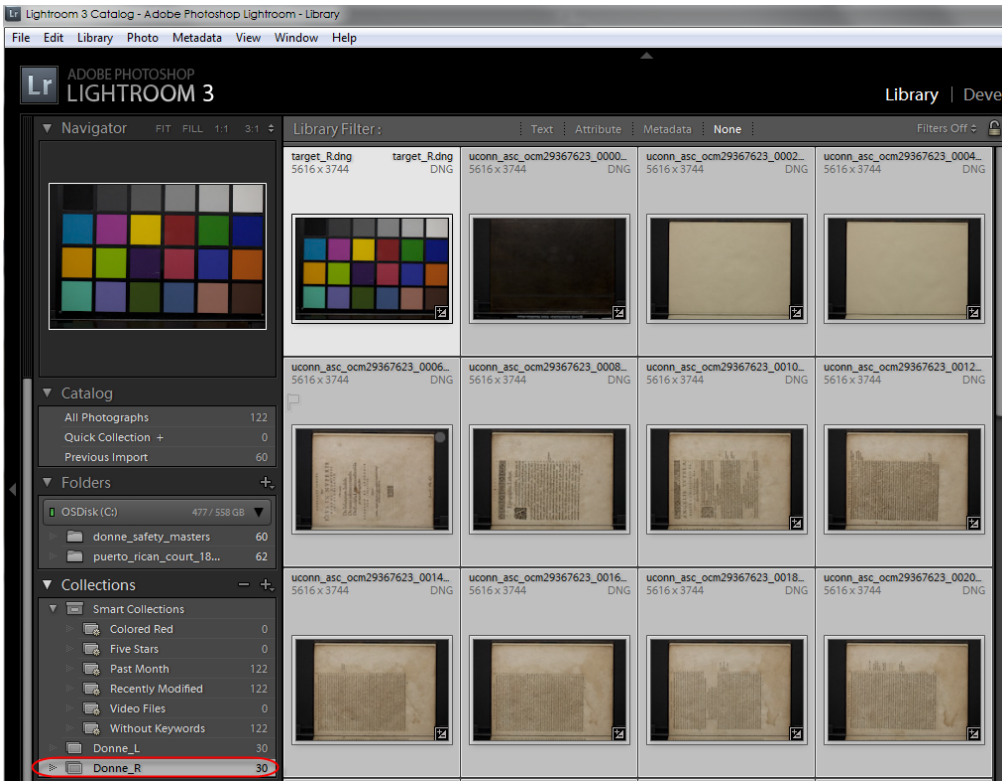

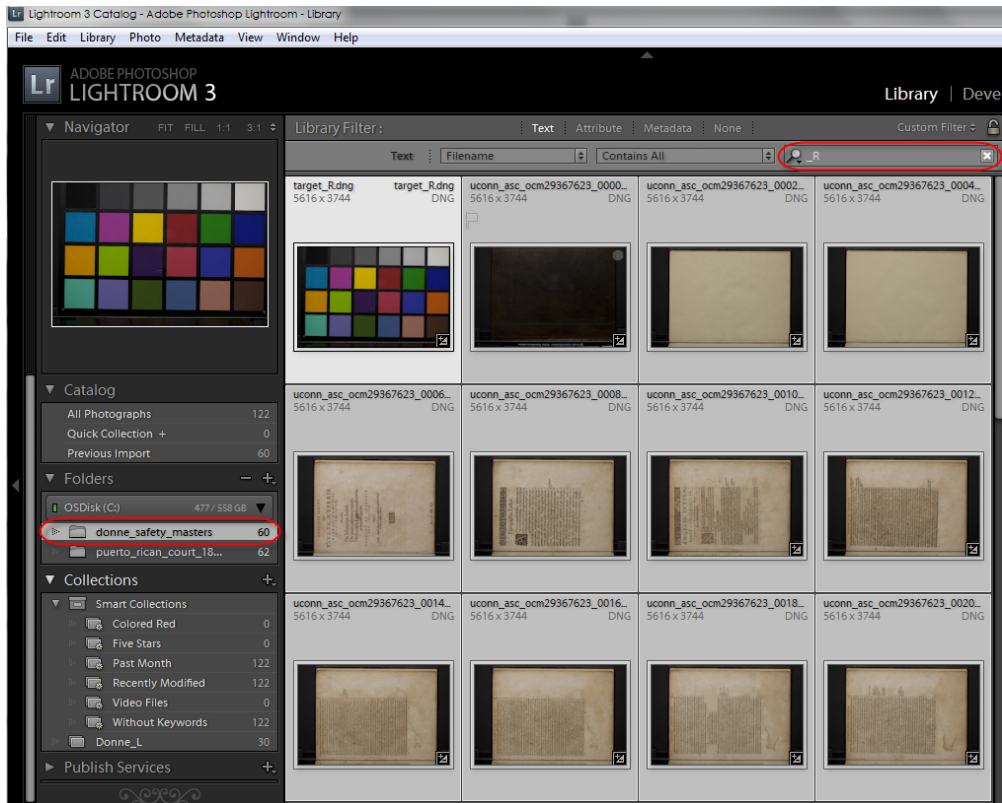

batch processing, then, left and right images are captured with \_L and \_R file name suffixes respectively through Atiz BookDrive Capture software. Lightroom can then easily filter by file name suffix and segregate images into left and right image collections where batch clockwise or counter-clockwise rotation and cropping steps can be parametrically run on the DNG files in a quick, lossless manner.

Figures 5. With all images still selected, a Lightroom Filename text filter for “\_L” is applied.

Figures 6-8. Filtered images are then added to a new Lightroom collection for editing.

Figures 9-10. Similarly, by navigating back to the original safety masters folder all files can then be selected and filtered by “\_R” with the results placed in their own “\_R” collection, separate from the “\_L” pages.

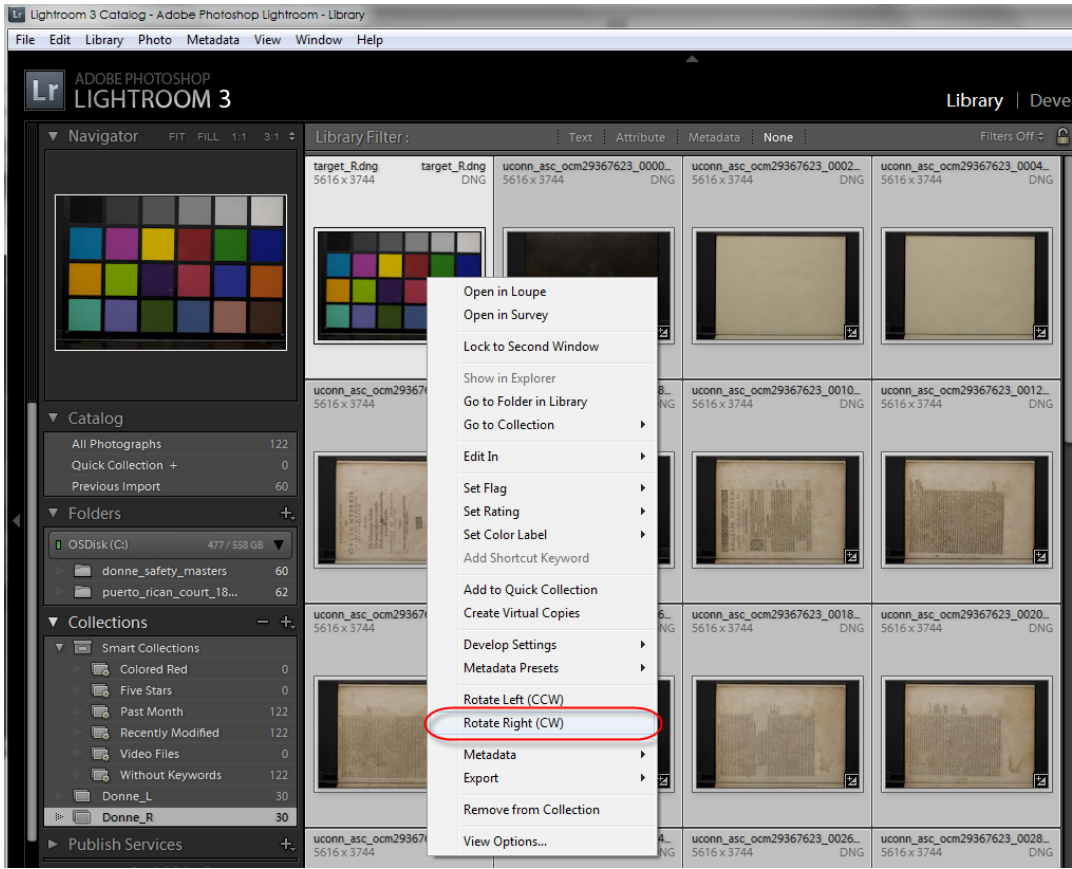

Figure 11. All images in the Donne\_R Collection are rotated right.

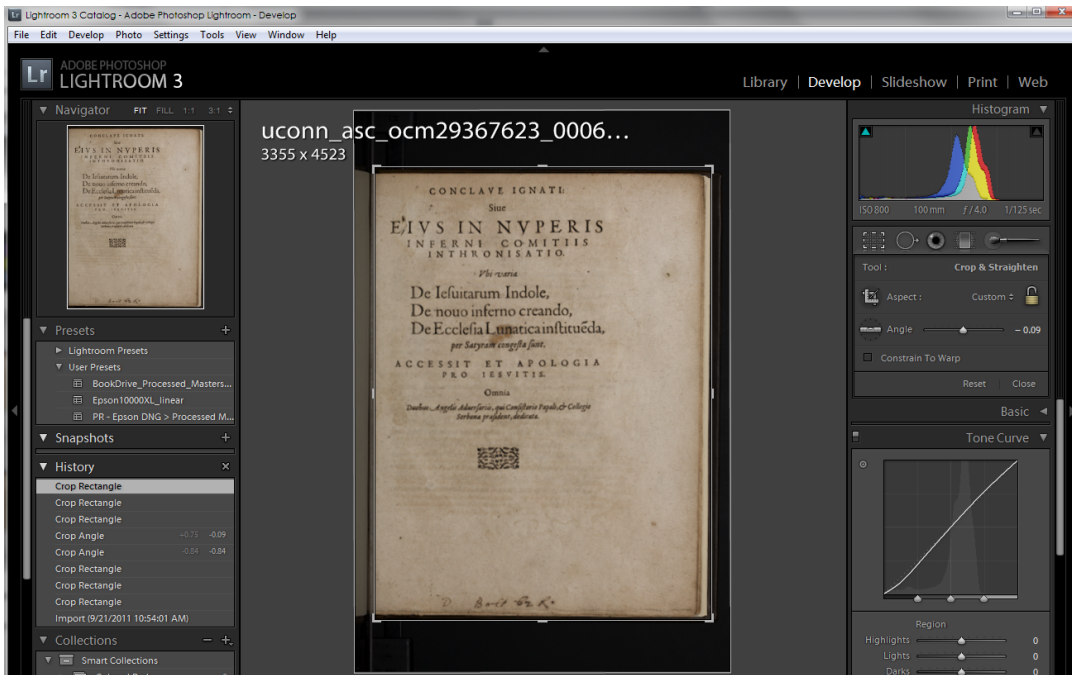

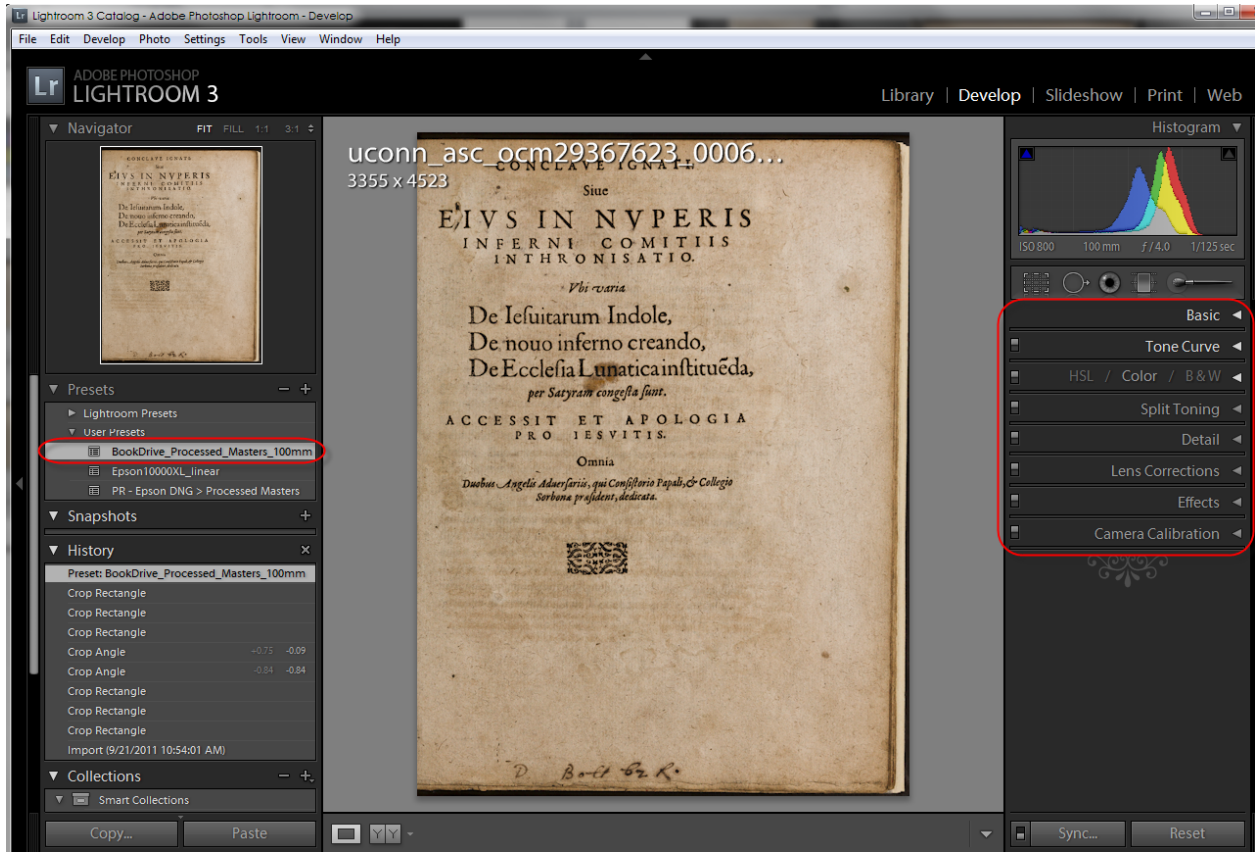

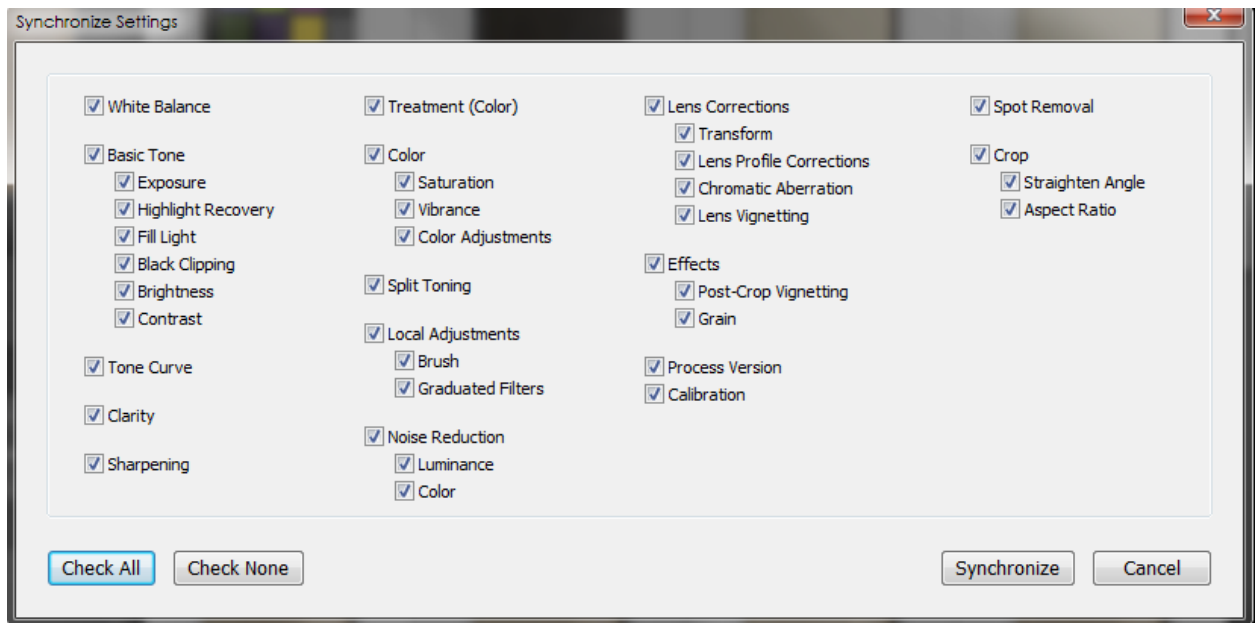

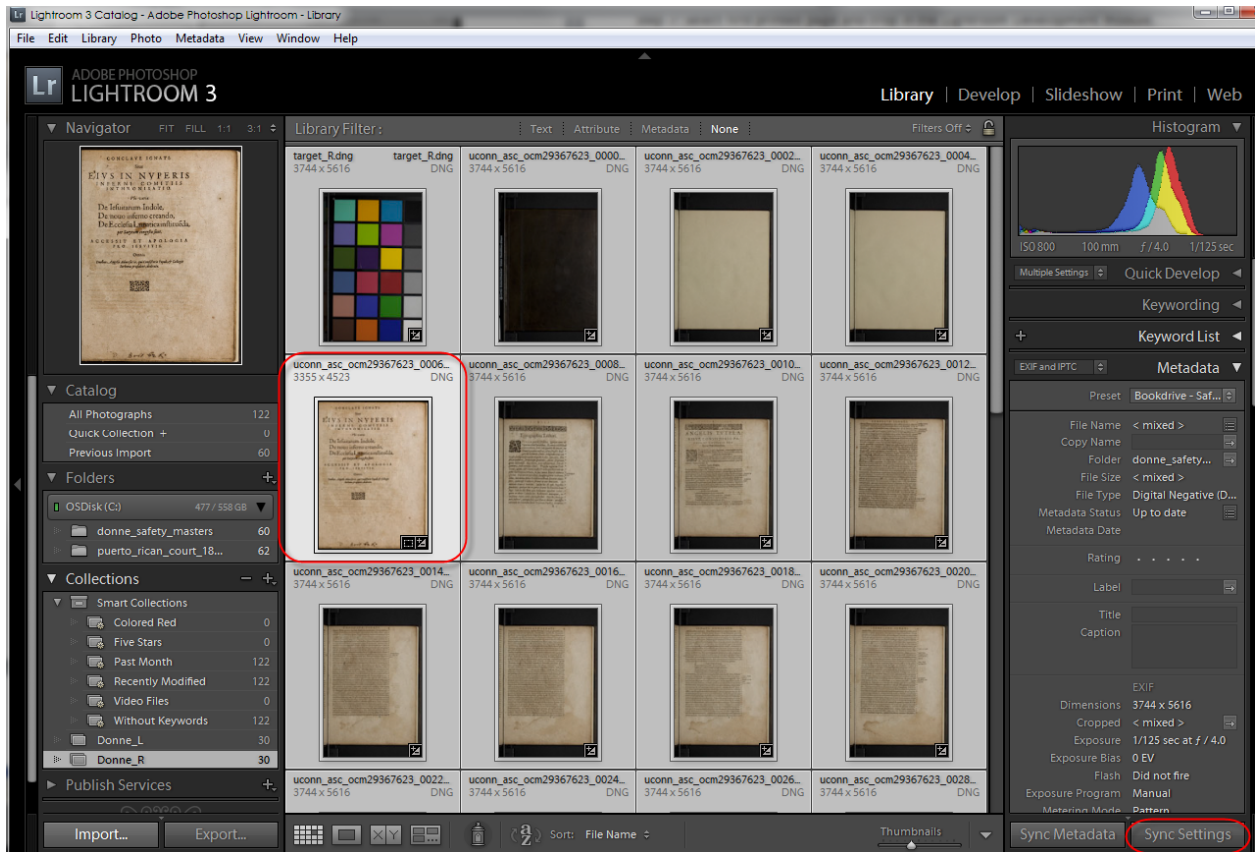

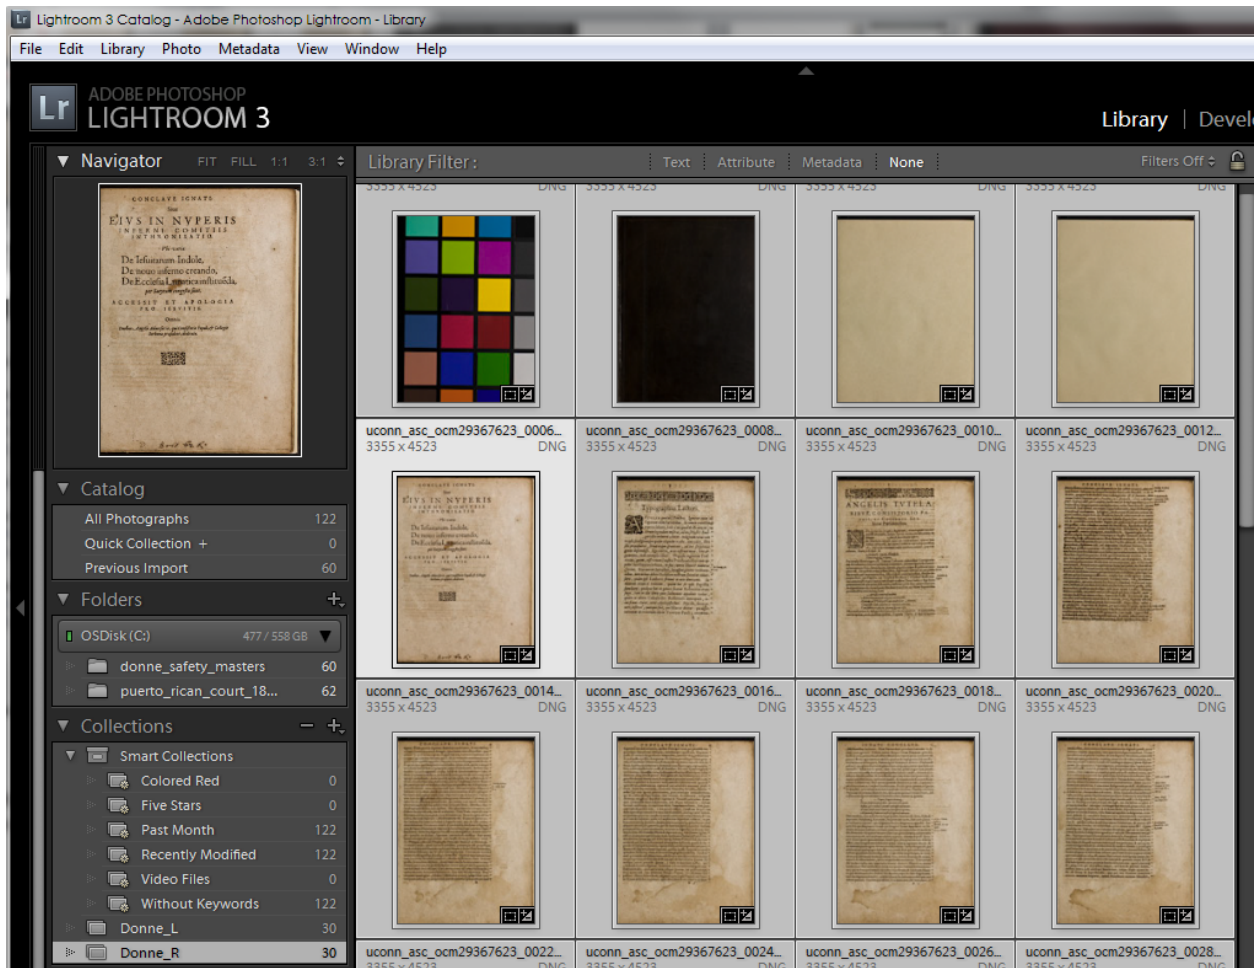

Figure 12. The first printed page is selected and cropped in Lightroom's Develop module.

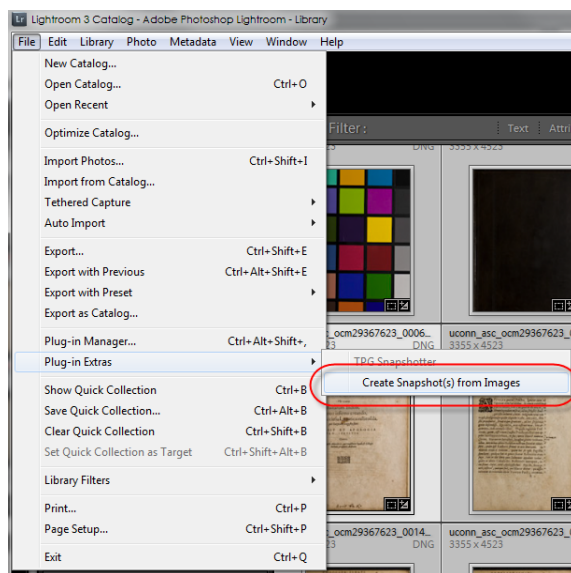

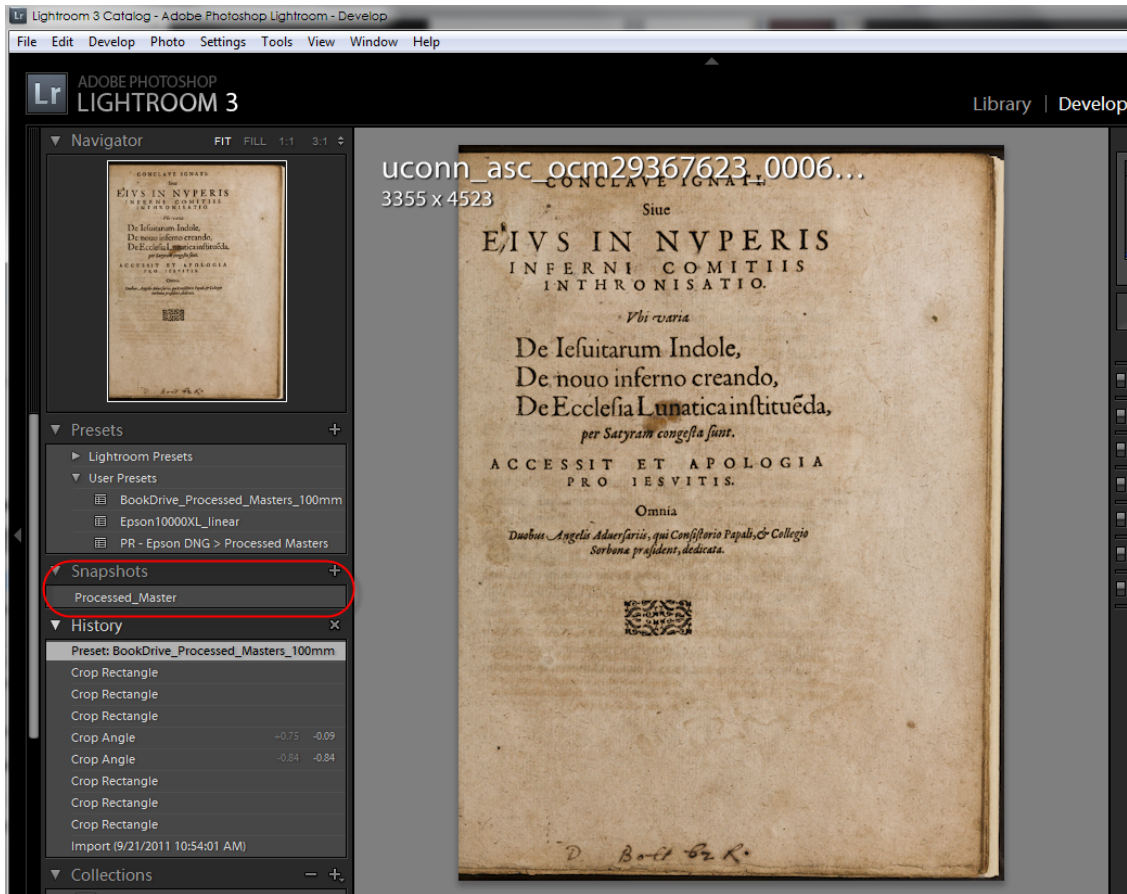

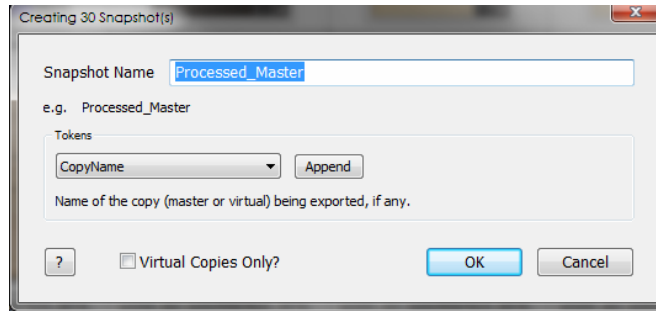

**Figure 13.** The page image is further enhanced from either its near linear (zeroed) or Lightroom's shipped default settings state to better meet project reformatting needs as appropriate. Here a previously-created development preset is applied to the image with the main goal of improving text contrast for enhancing downstream OCR success, while also mitigating paper color shifts from such strong tonal adjustment.

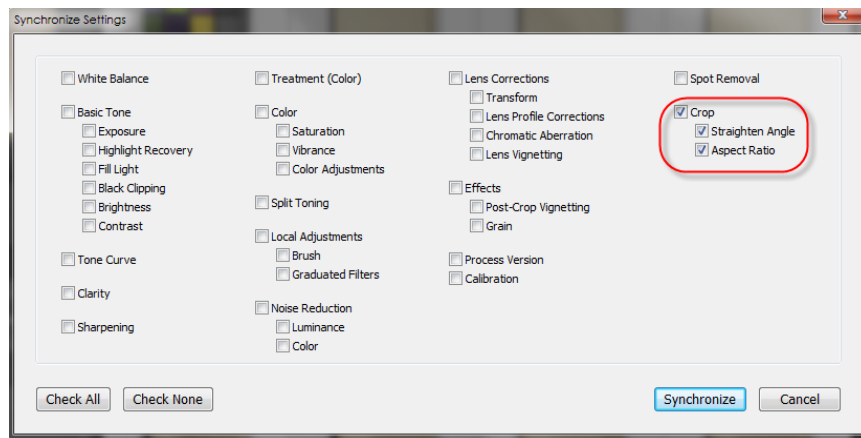

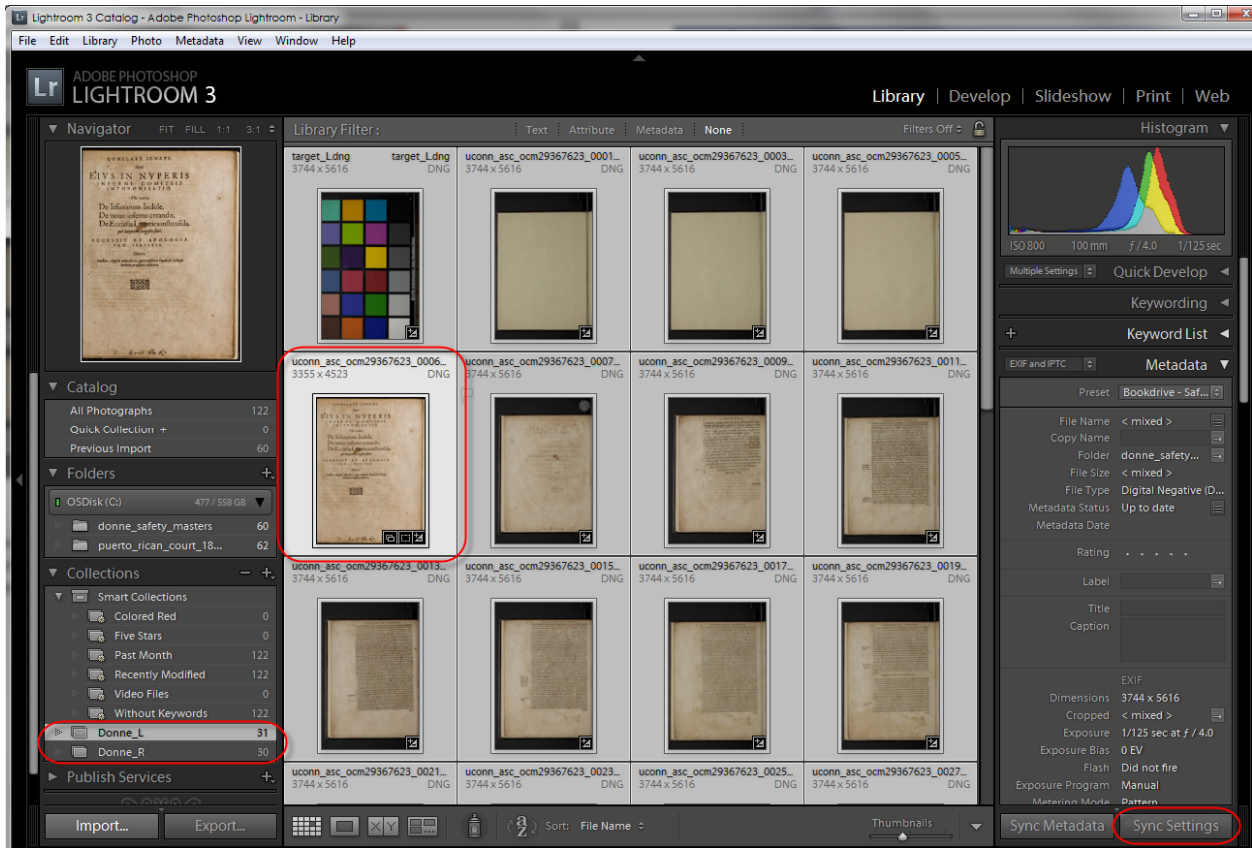

**Figures 14-16.** Back in the Library Module, Sync Settings is applied from the just-edited and still active page image to the other selected images in the *\_R* Collection in order to copy both the cropping and development settings just made. Crop boxes are re-aligned (but not resized) on individual images as needed in the Develop Module.

**Figures 17-19.** A “Processed\_Master” Snapshot is batch assigned with the Snapshotter plug-in [11] to all edited images in order to better secure and manage particular parametric processing adjustments. Through the application of Snapshots, which can embed such instruction sets into the DNG files themselves, various DNG edited “states” [12][13] can be easily called up in Lightroom (or Adobe Camera Raw). From multiple selected DNGs, Snapshot-controlled “states” can then be quickly batch exported on demand as converted raster formats for various purposes (e.g. “Processed for Text Enhancement,” “Processed for Print Reproduction,” “Scene Referred State,” “Zeroed or Linear Latent State,” etc.). See loose manuscript workflow in next section for another example of the use of Snapshots.

**Figure 20-21.** The other \_L Collection is navigated to in Library Module, where all images are subsequently selected and rotated. One of the images from the \_R Collection is then added to the \_L Collection. The Crop setting alone from the added image is synced to the rest of the \_L Collection's images. This ensures that page sizing is the same among both right and left hand pages. The \_R active image is then removed from the \_L Collection. The crop box on one of the new images is re-aligned and then re-synced among just the \_L images. The same Develop Preset used previously on the \_R Collection images is applied to one image, and then Sync Settings is applied to all images in the \_L Collection. A "Processed\_Master" Snapshot is added to all \_L Collection images with the Snapshotter plugin as described earlier. Finally, still in Lightroom, the safety\_master folder is navigated to in order to examine both right and left edited pages together in filename order. Once it has been determined that all images are satisfactory, both the \_L and \_R Collections are deleted.

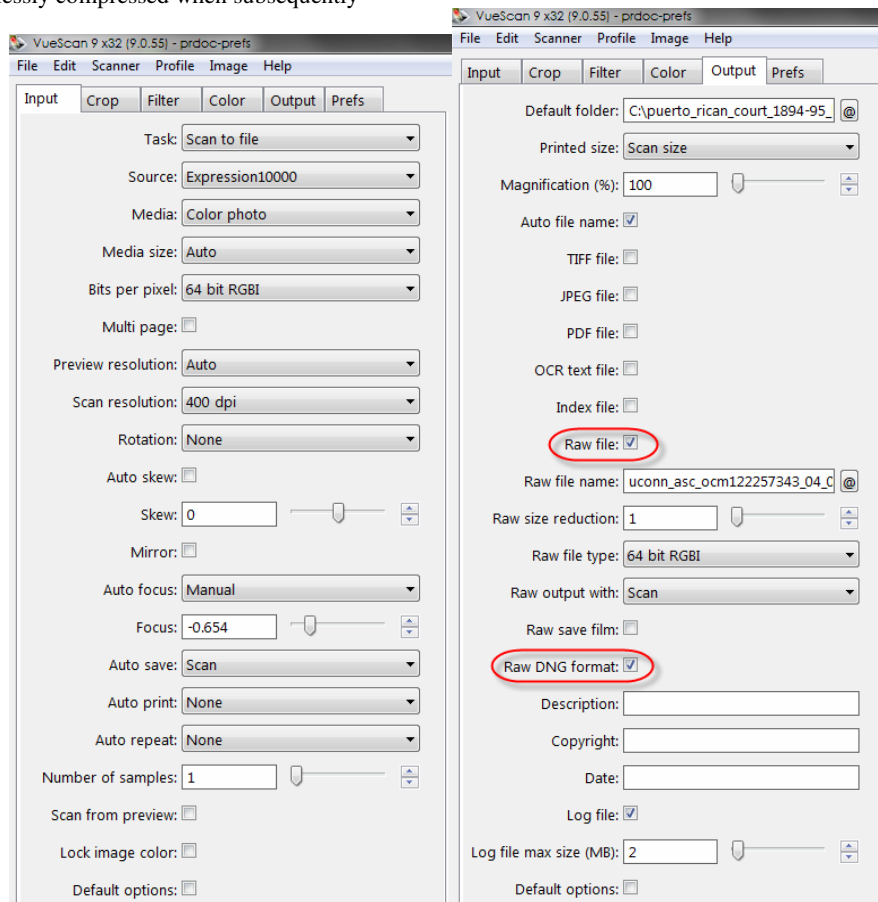

### **Loose Manuscript Page Workflow: DNG from Scanner Trilinear Array Sensor Data**

DNGs can also be created directly from scanners through the use of VueScan software. In this way a measure of parametric editing workflow and image format continuity can be coordinated among a conversion lab's given range of capture devices. As a result, aspects of batch parametric processing need not be completely re-written from scratch for each equipment type but can be re-purposed and shared among a broader spectrum of cameras and scanners.

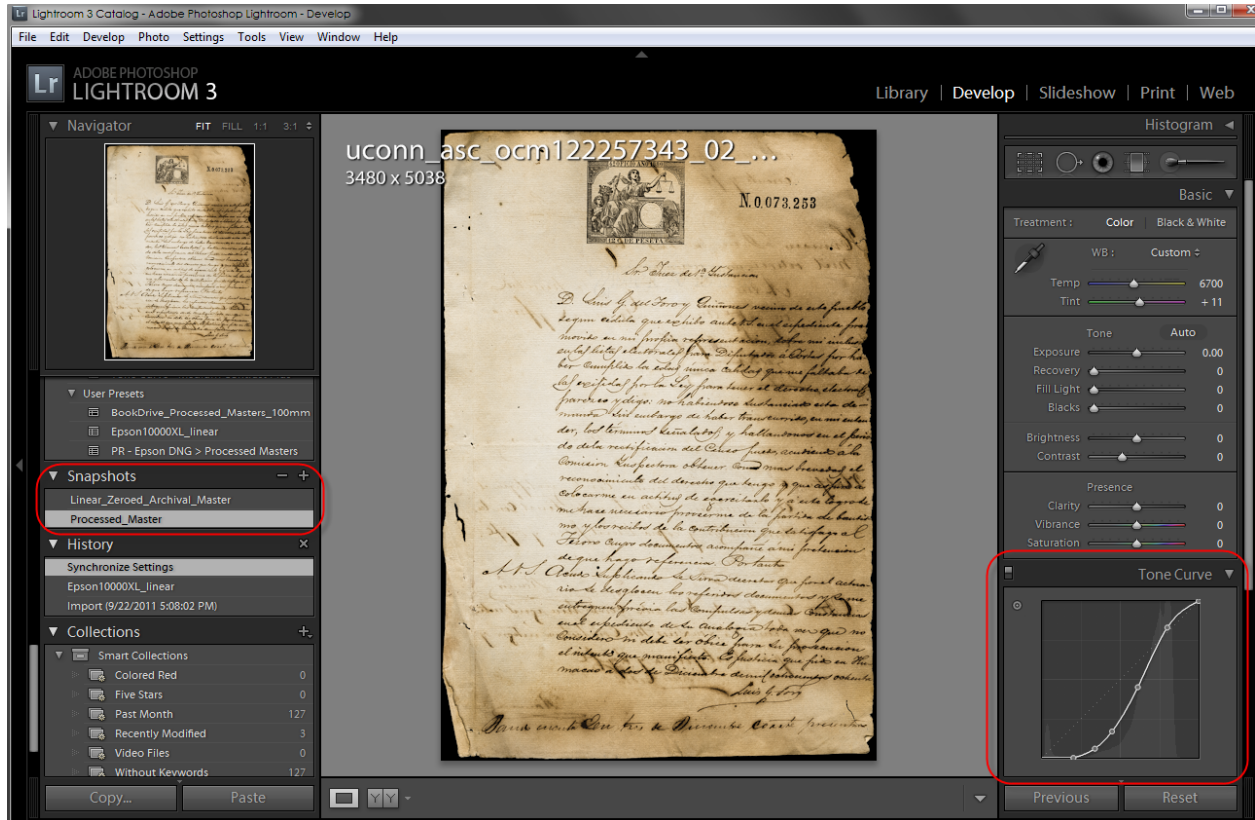

It bears noting that as opposed to color filter array (CFA) sensor devices like the majority of today's digital cameras, common flatbed scanners employ a trilinear array of RGB-filtered CCD sensor elements [14]. In turn, unlike CFA-based camera DNGs which contain mosaic sensor data, native scanner DNGs are linear encoded RGB files at inception. Such linear (gamma 1.0) DNGs, however, still enjoy many of the same lossless parametric editing efficiencies as camera-based DNGs when manipulated in tools like Lightroom, Adobe Camera Raw, Bibble, etc. In addition, VueScan's default uncompressed DNGs can also be losslessly compressed when subsequently

batch processed through such tools or Adobe's DNG Converter. The resulting storage savings of losslessly compressed DNGs (see chart in next section) scale favorably in terms of high volume conversion projects. Also, planned project capture standards may more easily sway towards higher resolution and/or greater bit depth aims since such choices can be less dictated by the elevated storage costs of traditional uncompressed TIFF creation and be more focused on the overall goal of high-quality imaging.

As previously illustrated and in the following demonstration, DNG can be flexibly leveraged across a broad array of project and operational aims. In contrast to proprietary raw specifications, DNG's openly documented architecture uniquely allows the format to be coherently preserved and predictably re-used across platforms and applications. Through the utilization of parametric signposts like "Snapshots," a variety of edited "states" along with various software processing versions can begin to be managed consistently through time.

**Figure 22.** VueScan v9.0.55 Settings for DNG scanner capture.

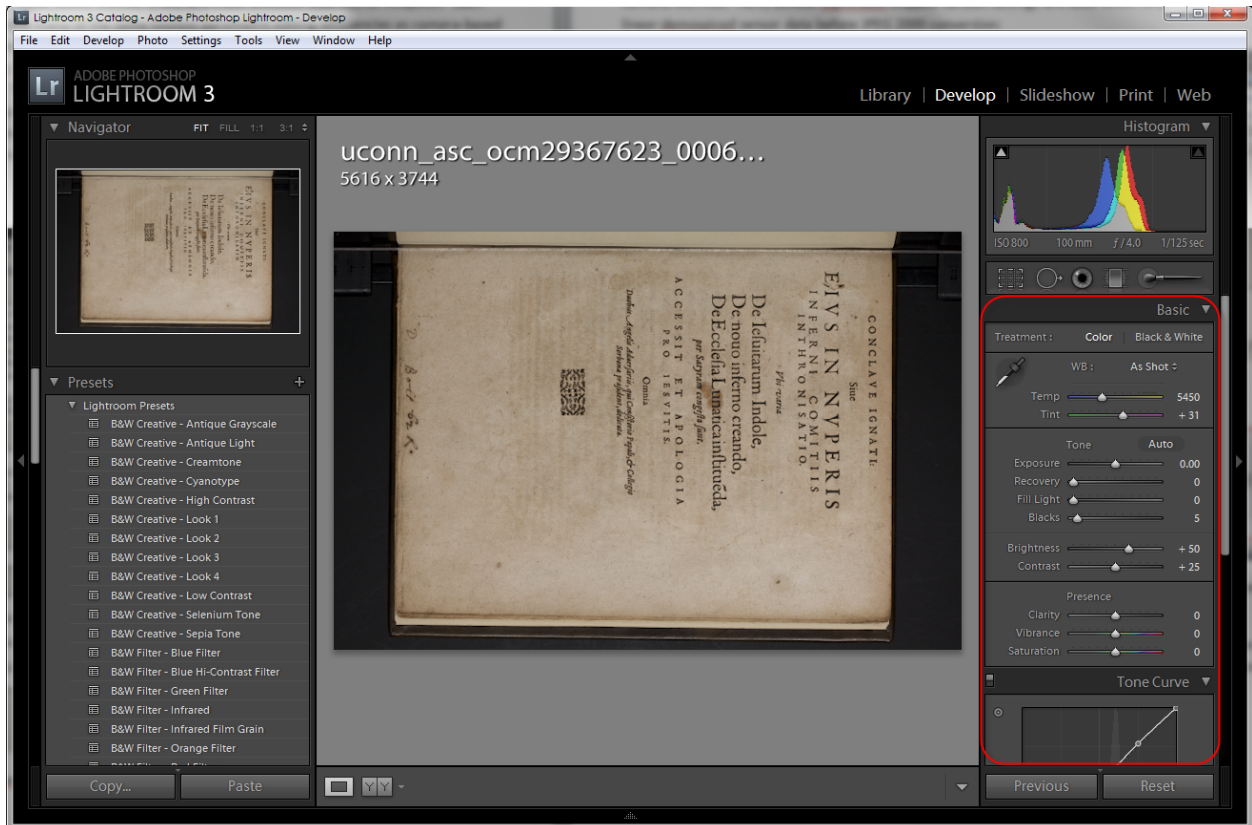

**Figure 23.** Saved Snapshots for sample scanner DNG from a 19<sup>th</sup> century Puerto Rican civil court manuscript reformatting project. In this example, the *Processed\_Master* Snapshot is activated and shows the steep parametric tone curve applied to the manuscript to better enhance front-side handwritten legibility from backside handwritten bleed-through. Additional parametric Color adjustments include both negative Hue and negative Saturation to Yellow that are used in order to better manage resulting paper color shifts that result from previous tone curve handwriting enhancements.

## Lossless JPEG 2000 as Raster Archival Master File Format Alternative to TIFF

One of the simpler ways to begin to explore the advantages of JPEG 2000 is to consider its losslessly compressed use as an archival raster format substitute to uncompressed TIFF. On average, a given lossless encoded JPEG 2000 file will be 1/3 the size of the same image saved as uncompressed TIFF all without loss of any image information. When factored into a given

institution's total number of archival image files, substantial, scalable data storage savings can be readily achieved.

Lossless JPEG 2000 files can be batch-created directly from camera raw files or converted DNGs in the following automated manner.

**Figure 24.** A determination of what level of processing, if any, is made for the raw files prior to JPEG 2000 conversion. Here, Lightroom's shipped default presets are shown which employ gamma correction to the near linear demosaiced sensor data and can be synced to all monograph raw images prior to JPEG 2000 conversion. For more specific scene-referred JP2000 rendering, more fine-tuned presets can be created, stored, and likewise synced.

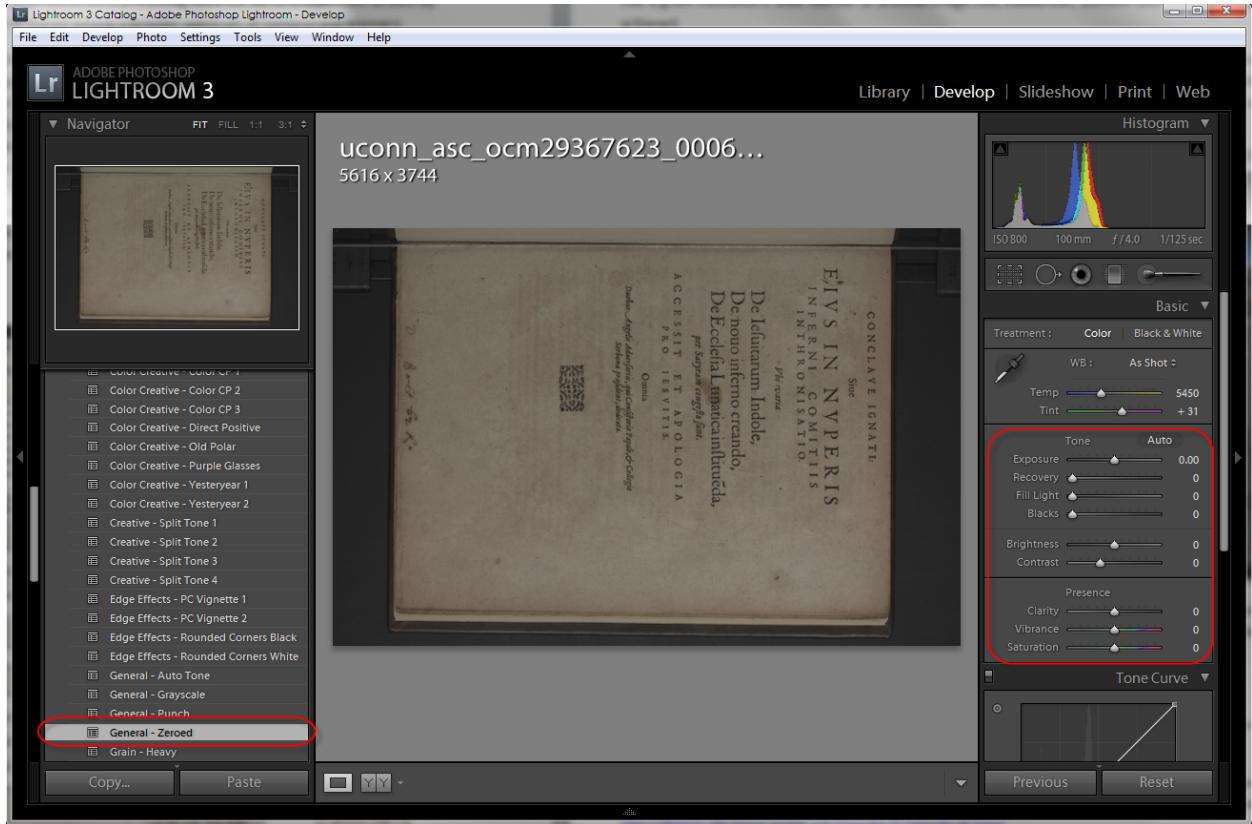

Figure 25. Or all raw images can be “zeroed” before JPEG 2000 conversion which in essence leaves the raw files in a near latent, linear state.

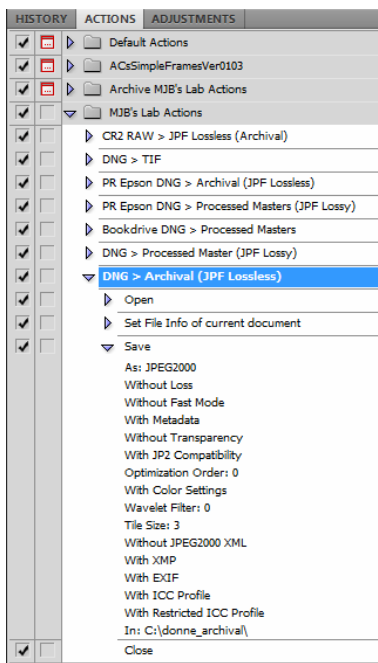

Figure 26. A Photoshop action for DNG > lossless JPEG 2000 conversion is created. (Note: source and destination folders used while creating the action are irrelevant. See next steps.)

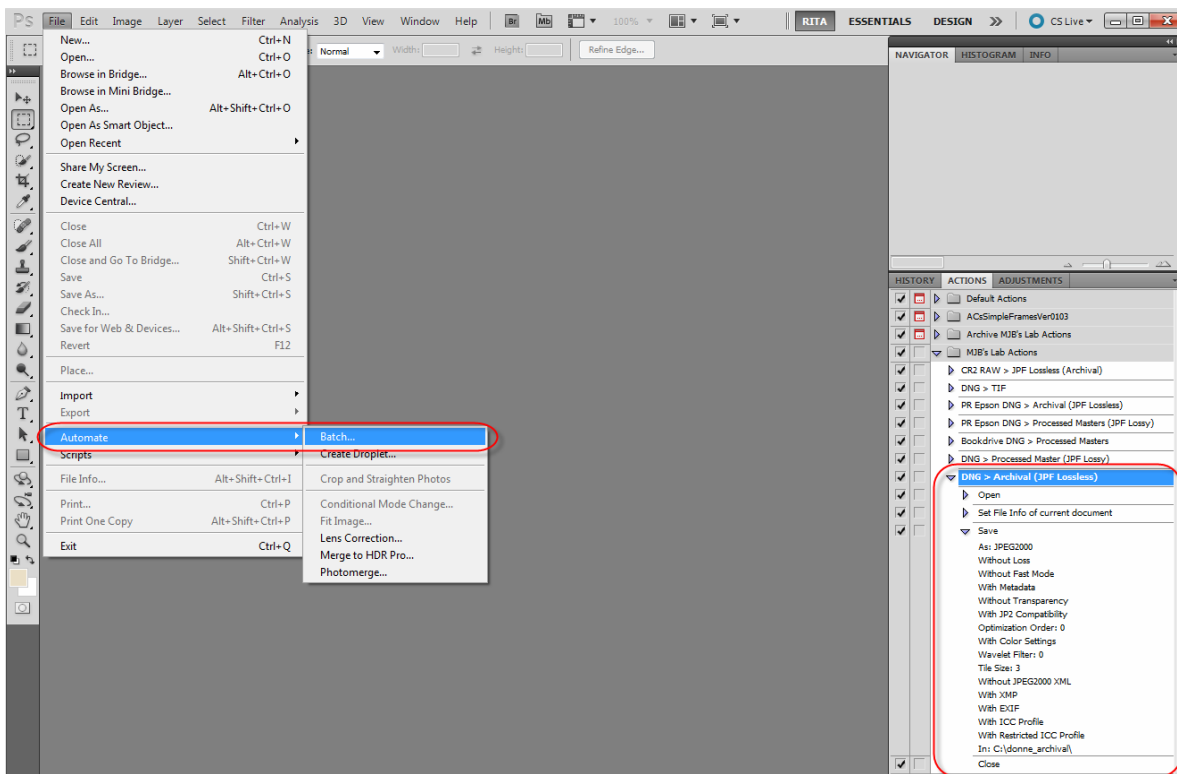

Figure 27. A destination folder is created for the JPEG 2000 archival files that are about to be encoded (e.g. book\_title\_archival). Photoshop is then opened. The "DNG > Archival (JPF Lossless)" action is chosen. File > Automate > Batch. DNG > Archival (JPF Lossless) action should be pre-selected.

```

**Figure 31.** From the resulting C:\Jhove\_JP2\_Audit\_rpts folder, the .txt file inside is then opened to view errors. "Not well-formed" is an error, "valid" is a good file. The numbers at the bottom of the report indicate that out of 16 files, 15 were good and 1 was bad. Any bad files are re-encoded, and then the audit steps are repeated once again until no errors occur. (Note: Bad file was manually corrupted in figure above prior to audit checking for illustration purposes). The c:\book\_title\_archival folder is finally copied to archival storage, and then deleted from C:\ drive.

The following illustration summarizes some of the scalable storage advantages of archiving both lossless JPEG 2000 [17] and raw DNGs for a given camera image vs. uncompressed TIF. By taking advantage of the lossless compression efficiencies of DNG and JPEG 2000, institutions not willing at this point in

time to only save raw files can still reap the robust data preservation and processing gains of raw while maintaining the traditional benefits of rendered still image archiving. Significantly, this can all be achieved while taking up less storage space than a single uncompressed, rendered TIF.

## Lossy JPEG 2000 Processed Master File Format

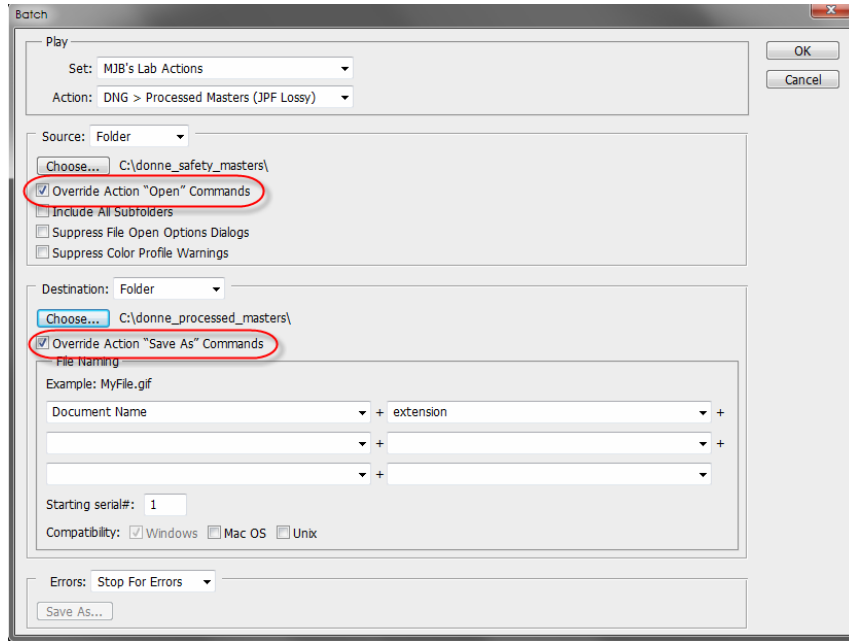

Through collaboration with software engineer, Hank Bromley, from the Internet Archive (IA) the author has tailored the UConn lab's monograph and manuscripts workflows to integrate with IA's batch ingest protocols. This has allowed the UConn Libraries' lab to function much like an IA scan center for online delivery of these material types. Part of this process is the creation of lossy (but visually lossless) JPEG 2000 processed master files, grouped into .tar files, one "tarball" of all page images per monograph volume. Lossy, irreversible JPEG 2000 is chosen because of its possible visually lossless compression and highly efficient storage savings which scale favorably across all aspects of the combined workflow (i.e. tarball upload, local and IA archiving, automated IA OCR, IA eBook format encodings, and interactive online "bookreader" interface generation). An example of the final results for one

volume may be viewed at

<http://www.archive.org/details/conclaveignati00donn>.

DNG Safety Masters with "Processed\_Master" Snapshots are the source for such rendered JPEG 2000 processed master images. The DNG Snapshots normally represent the source images parametrically rotated, cropped, with applied tonal adjustments best suited for high OCR success as described earlier. Lossy, but visually lossless, JPEG 2000s are then batch created along with embedded technical metadata through Photoshop from the DNGs in the following way.

**Figure 32-33.** In Photoshop, “DNG > Processed Master (JPF Lossy)” action is selected. File > Automate > Batch is navigated to in order to apply above action and create JPEG 2000 processed masters from DNG files’ “Processed\_Master” Snapshots. A Jhove Audit on the resulting new JPEG 2000 processed masters is then run to check for encoding errors. Any bad files are then re-encoded, and the audit process is repeated until no errors occur.

**Figure 34.** Files are renamed with jp2 extension for broader ease of use. Note: this step is possible because original .jpf files are batch encoded with “JP2 compatibility” (see Photoshop action save step). The c:\book\_title\_processed\_masters folder is copied to archival storage. c:\book\_title\_processed\_masters is then deleted.

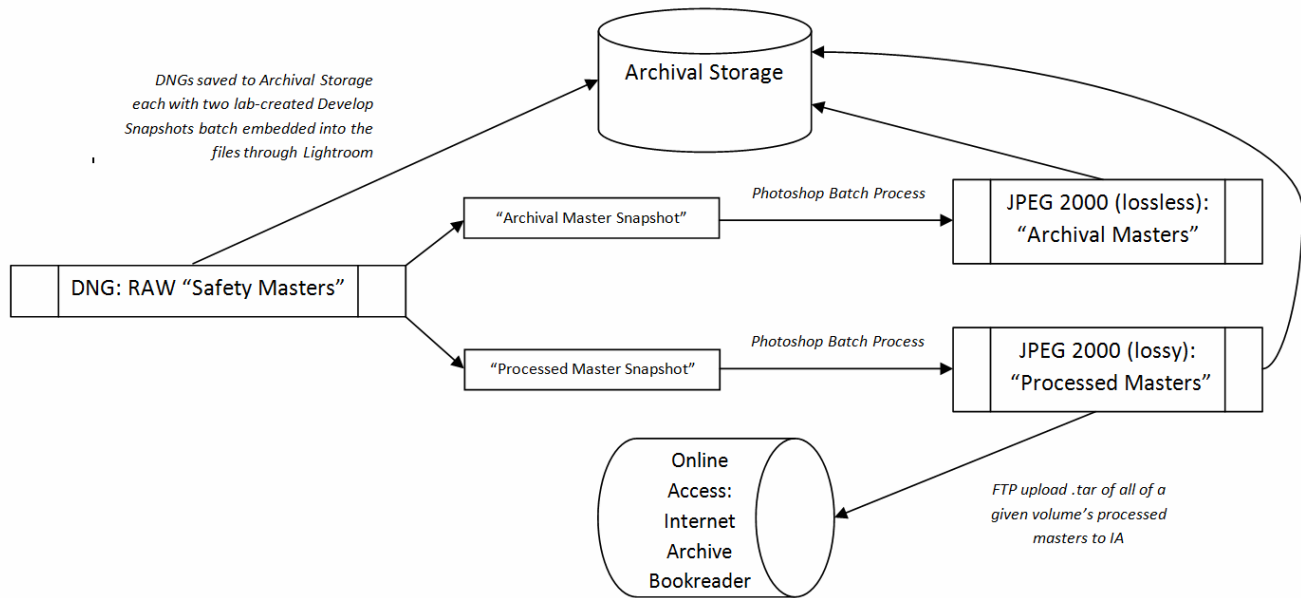

Figure 35. Schematic View of UConn Monograph Conversion Workflow

## Leveraging Embedded Process Metadata in XMP

File-embedded XMP and its support for IPTC Core opens up new opportunities to create more robust still image files [18][19][20]. Such files can contain not only device-generated Exif information and parametric editing instruction tags (including Snapshots), but can also contain IPTC Core elements that can be edited either individually in Photoshop or in batches through Lightroom metadata presets and/or Adobe Bridge/Photoshop metadata templates.

The advantages of such additional embedded descriptive metadata are many. Individual still image files can be less dependent upon traditional external catalogs for their descriptions and can in essence be self-describing assets with sufficient descriptive information. This is of particular interest as images are exported and re-purposed beyond the institutional gates of their creation and become de-coupled from their original hosted settings.

Important file creation information or "process metadata" can also be efficiently embedded to include details of technical provenance and image editing [21]. Such particulars can greatly assist in future large-scale migrations and/or accurate file replications as hardware, workstation OS, and post-processing software versions change through time.

Finally, once embedded in all files, both descriptive and technical process metadata greatly assist in original digital asset management (DAM) system imports and/or future DAM platform migrations. As the vast majority of DAMs move toward fuller XMP compliance, catalog database migrations and their inherent problems may be made easier with more fully self-described source files that in essence become their own best record. Additionally, XMP is serialized in XML and stored using a subset of the W3C Resource Description Framework (RDF) [22]. As such, XMP's structure incorporates well when

repurposed and leveraged through OAIS digital preservation technology stacks like Archivematica and repository frameworks such as Fedora.

What follows are examples of how the UConn Libraries' lab has begun to embed and standardize such metadata into the various still image files examined throughout this study.

## Conclusion

Today, recent developments in digital reformatting have included a growing movement toward making such conversions more broadly operational, larger scale, and systemic [23][24][25]. Simultaneously, as the software and formats that surround still imaging evolve, a greater need for more robust and flexible digital objects is becoming apparent to meet novel repurposing needs [26][27]. In turn, decisions with regard to the scalable use of raw still image file archiving and processing, and data compression in general are important to consider when both quantity and quality

are concurrent goals in today's reformatting ecosystem. Preserving the expertise of trained digital imaging technicians and the full sensitivities of the enlarging array of capture devices that they operate must be done now more than ever in both an efficient and extensible way to meet the requirements of feasible operational growth, new digital object use, and well managed storage over time. In so doing, institutions can more fully preserve and further utilize the fruits of their substantial investments in both digital conversion staff and equipment.

## Author Biography

*Michael J. Bennett is Digital Projects Librarian & Institutional Repository Coordinator at the University of Connecticut. There he manages digital reformatting operations while overseeing the University's institutional repository. Previously he has served as project manager of Digital Treasures, a digital repository of the cultural history of Central and Western Massachusetts and as executive committee member for Massachusetts' Digital Commonwealth portal. He holds a BA from Connecticut College and an MLIS from the University of Rhode Island.*
